

## Eclipse UOMo Tutorial

Eclipse UOMo is an API for working with physical quantities and units. We are going to create a demonstration application that provides an API to work with Newton's Second Law of Motion:

*"The acceleration of a body is directly proportional to, and in the same direction as, the net force acting on the body, and inversely proportional to its mass."*

Otherwise written as:

$$F = M \times A$$

Where:

F is Force in Newtons

M is Mass in Kilograms

A is Acceleration in Meters per second

Our example API will provide methods for computing any of the above, given the other two.

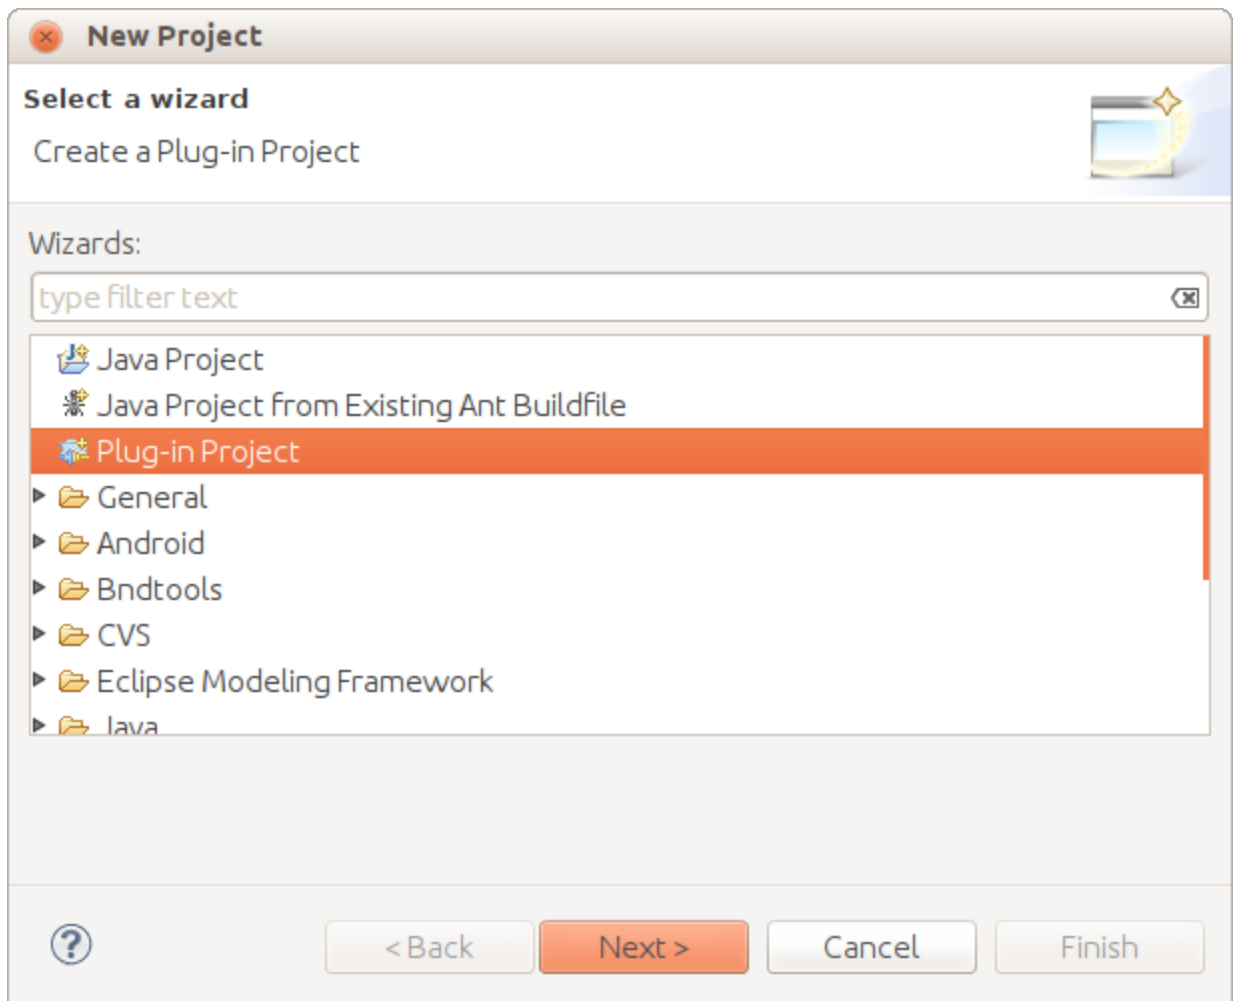

Example code for the following is available at GitHub:

<https://github.com/duckAsteroid/uomo-example>

## Getting Started - Eclipse Plugin Project...

Most of verbosity in the steps that follows are related to complexities of creating Eclipse plug-ins rather than anything hard about using UOMo...

1. In Eclipse click the File -> New -> Project.. menu
2. Select Plug-in Project:

Click "Next"

3. Enter a name for the plugin project (e.g. com.acme.n2l):

**New Plug-in Project**

**Plug-in Project**  
Create a new plug-in project

Project name:

☒ Use default location

Location:

**Project Settings**

☒ Create a Java project

Source folder:

Output folder:

**Target Platform**  
This plug-in is targeted to run with:

☒ Eclipse version:

☐ an OSGi framework:

**Working sets**

☒ Add project to working sets

Working sets:

Click "Next"

4. You can now customise the plugin details as follows:

**New Plug-in Project**

**Content**  
Enter the data required to generate the plug-in.

**Properties**

ID:

Version:

Name:

Vendor:  ▼

Execution Environment:  ▼

**Options**

☐ Generate an activator, a Java class that controls the plug-in's life cycle  
Activator:

☐ This plug-in will make contributions to the UI

☐ Enable API analysis

**Rich Client Application**

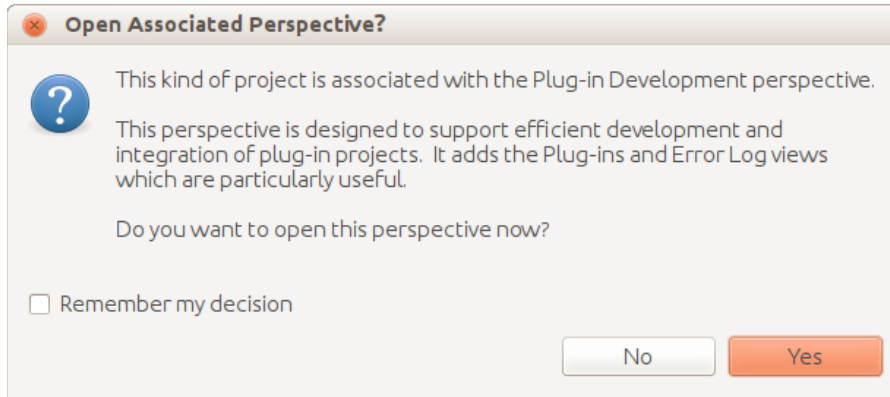

Would you like to create a rich client application? ☐ Yes ☒ No

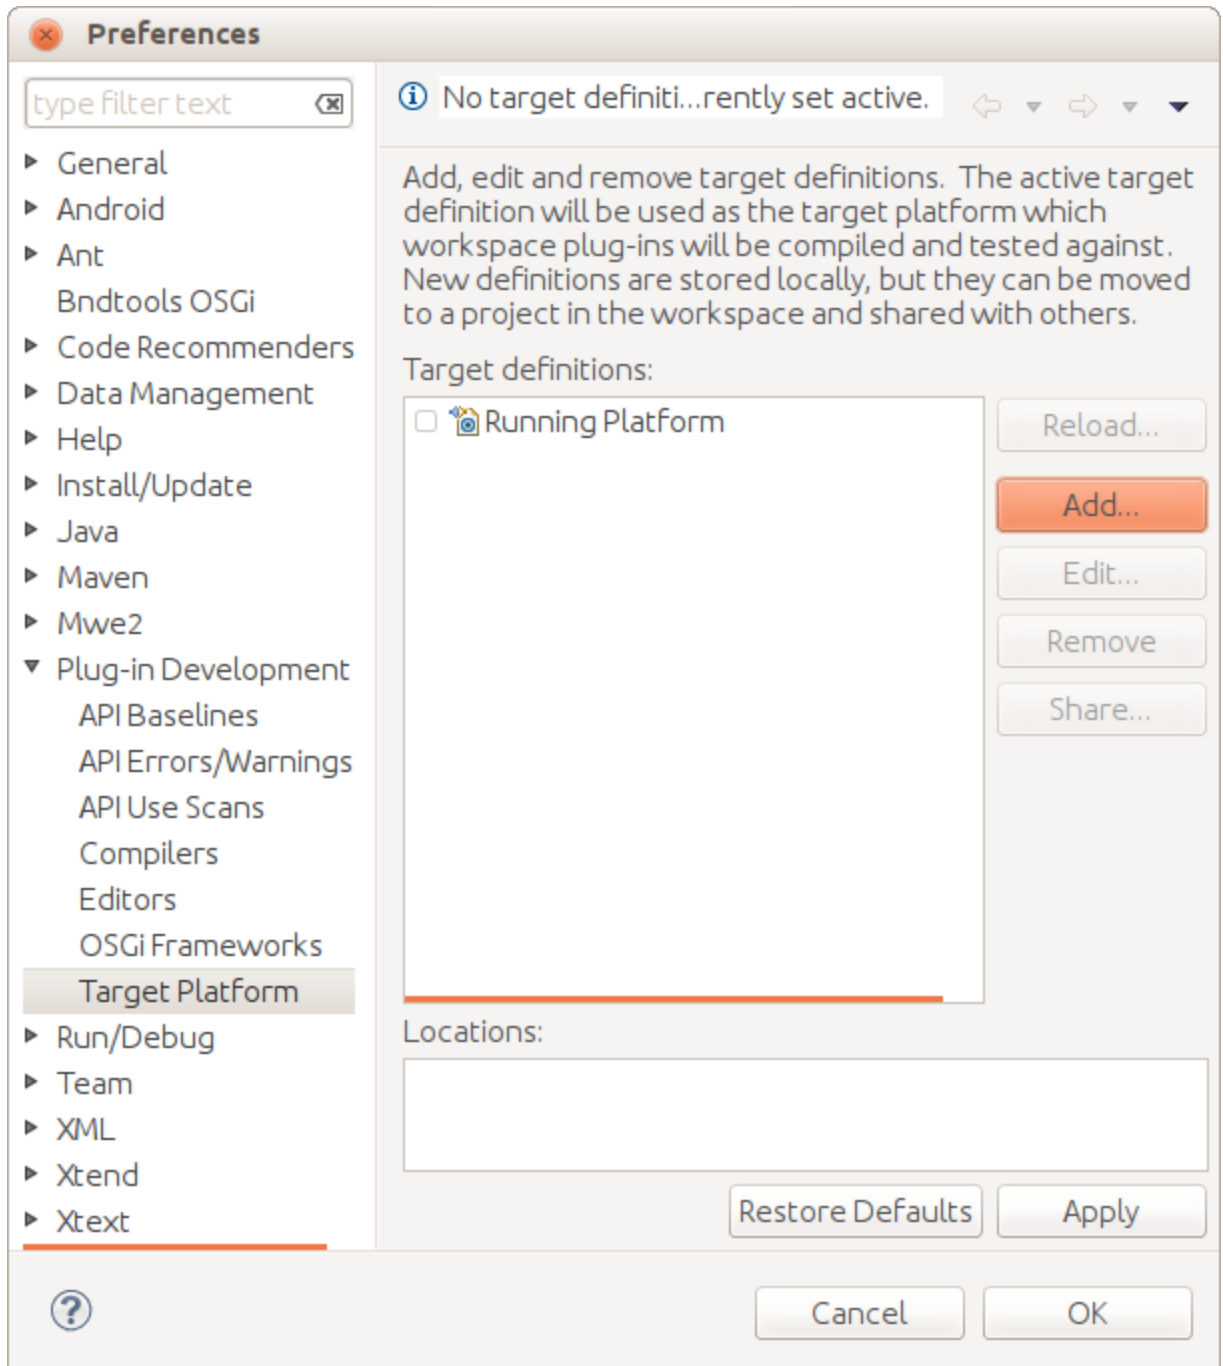

Ensure that all checkboxes under “Options” are de-selected.

Click “Finish”

If the following dialog appears click “Yes” to open the PDE perspective:

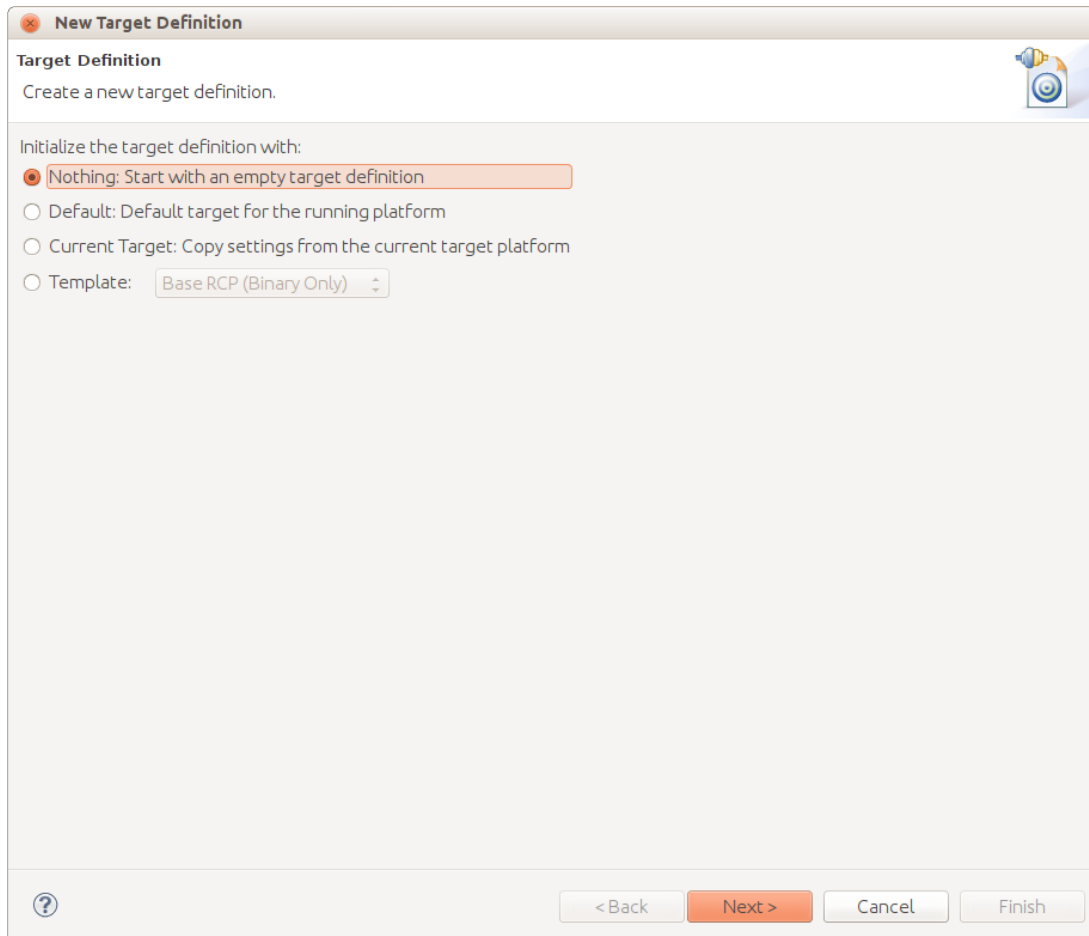

5. Eclipse will create your new project. Now we need to configure Eclipse so that it knows about UOMo and where it lives to build against.  
Click the menu "Window -> Preferences"
6. Navigate to the "Plug-in Development -> Target Platform" section of the preferences dialog:

Click "Add..."

7. Select "Nothing: Start with an empty target definition" in the "New target definition" dialog:

Click “Next”

8. Give the new target a name, such as “UOMo”:

**New Target Definition**

**Target Content**  
Edit the name, description, and plug-ins contained in a target.

Name:

Locations **Content** Environment Arguments Implicit Dependencies

The following list of locations will be used to collect plug-ins for this target definition.

Add...

Edit...

Remove

Update

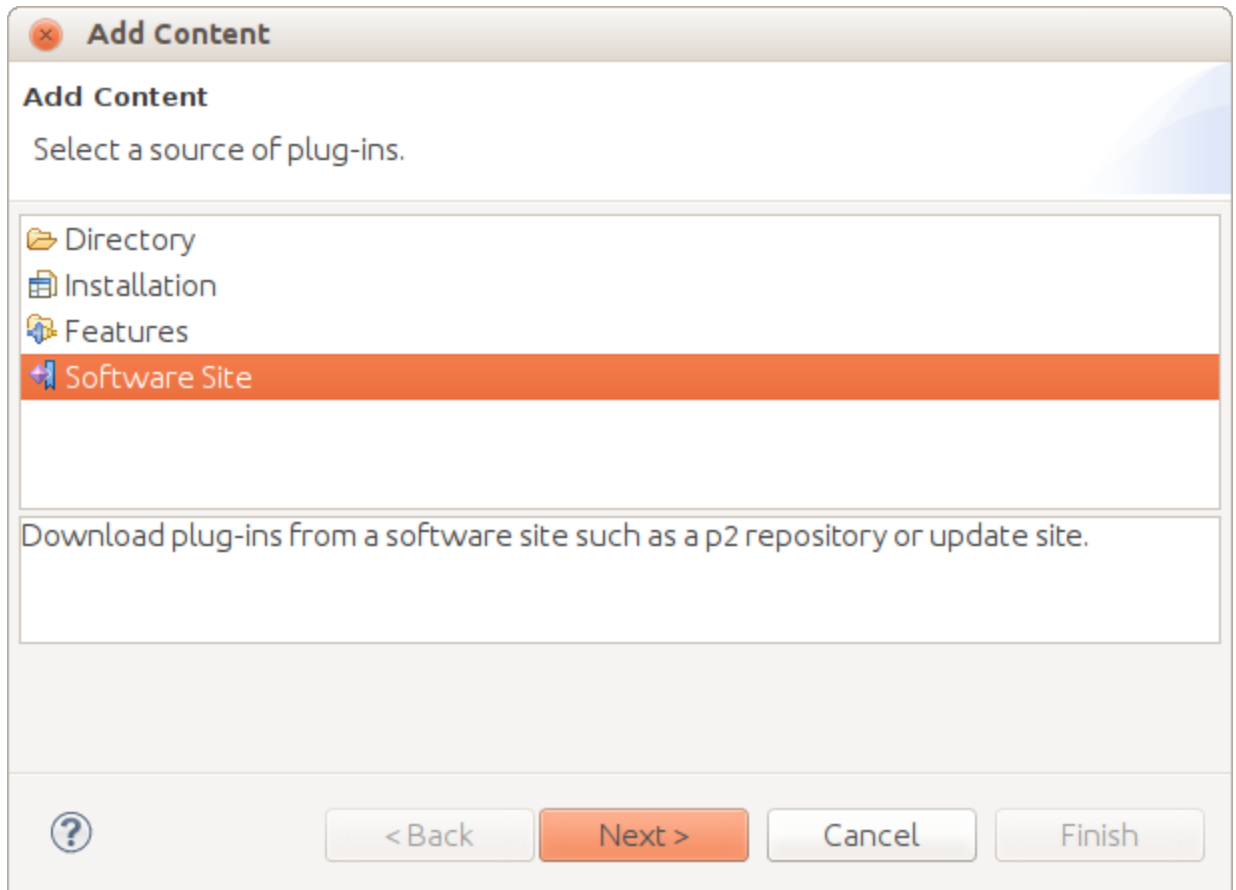

☐ Show location content

Click "Add..."

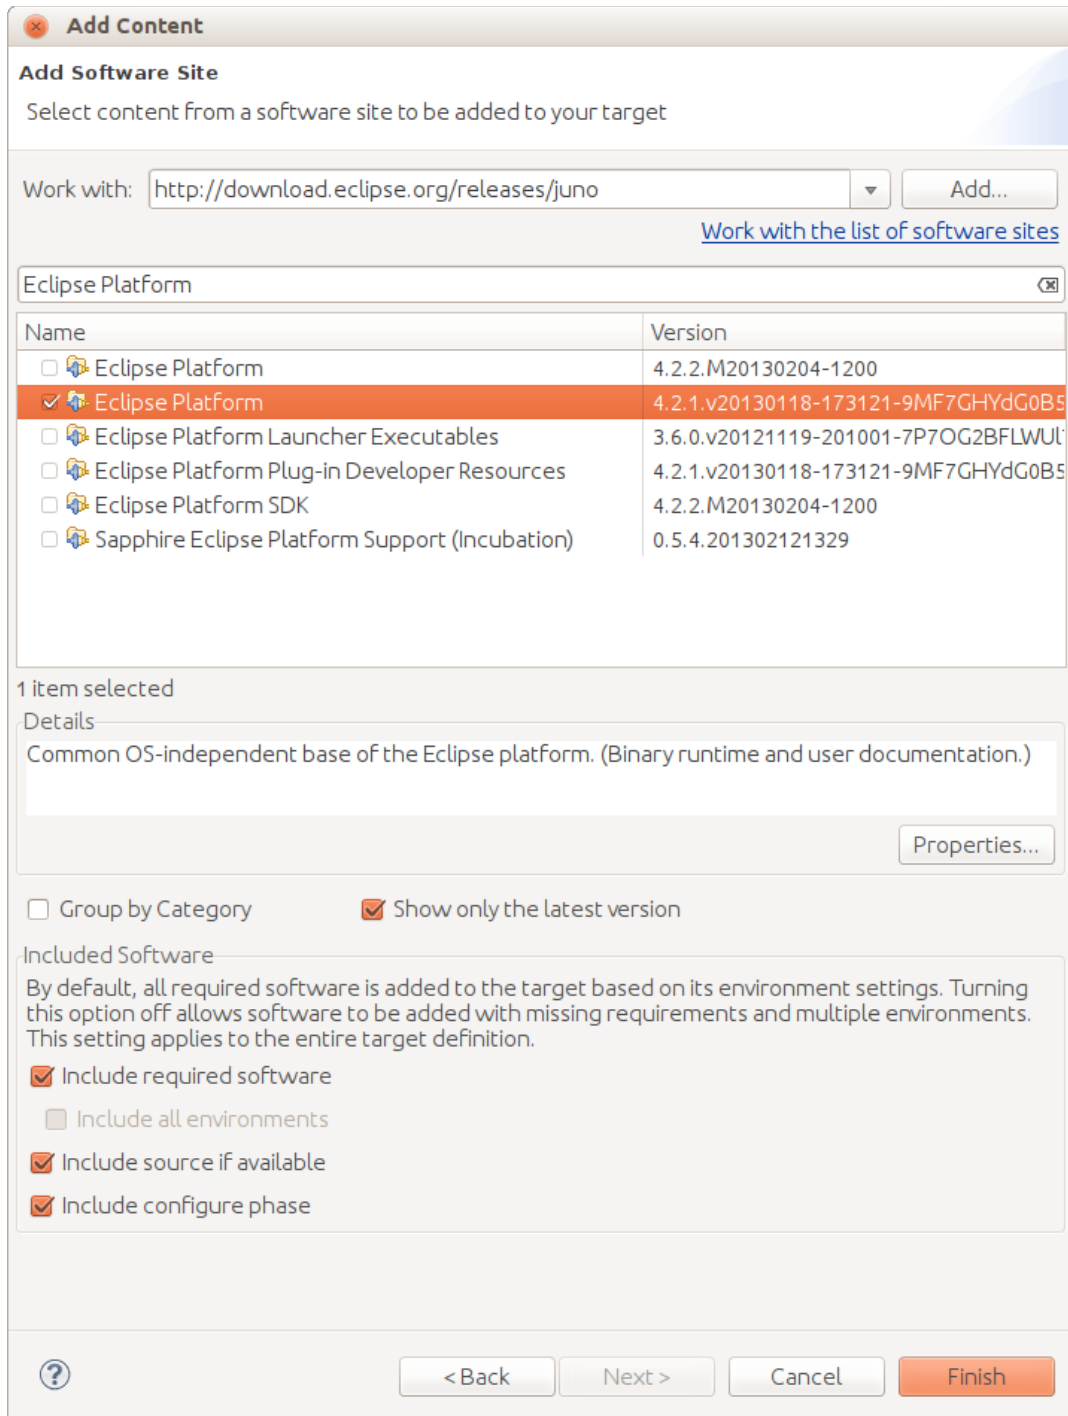

9. Select "Software Site" from the plug-in source options:

Click "Next"

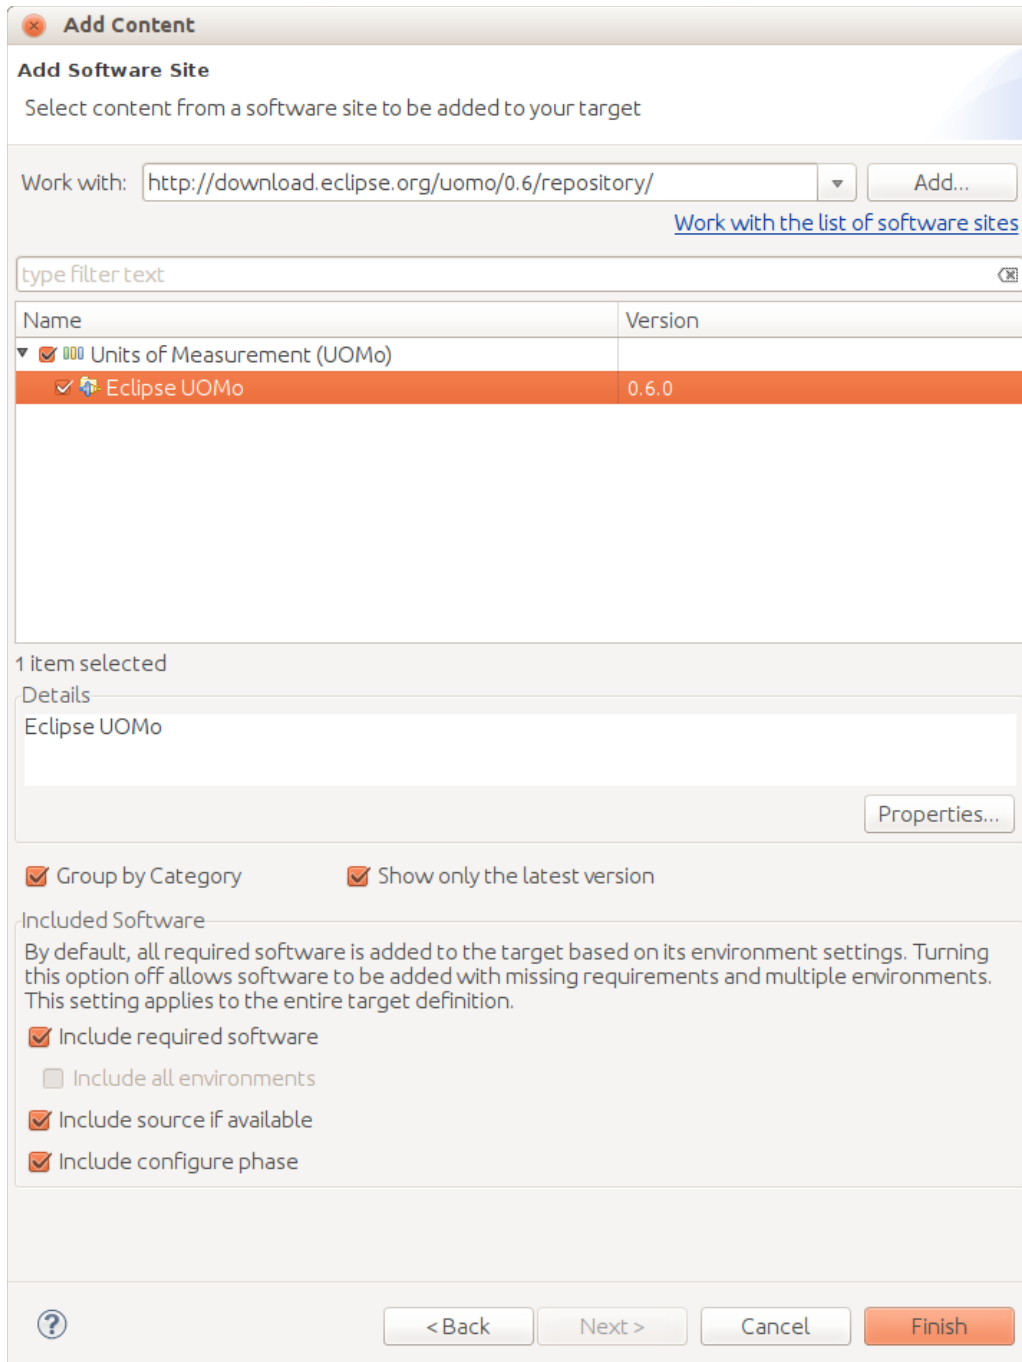

10. Firstly, we need to give our target definition a place to get Eclipse plug-ins from. Enter the URL <http://download.eclipse.org/releases/juno> into the "Work With" field. Ensure that the "Group by Category" field is un-checked.  
Type "Eclipse Platform" into the search field:

Select the Eclipse Platform (with out M\* at the end :- as this is a milestone release)  
Click "Finish"

11. Eclipse will do some loading/resolving...

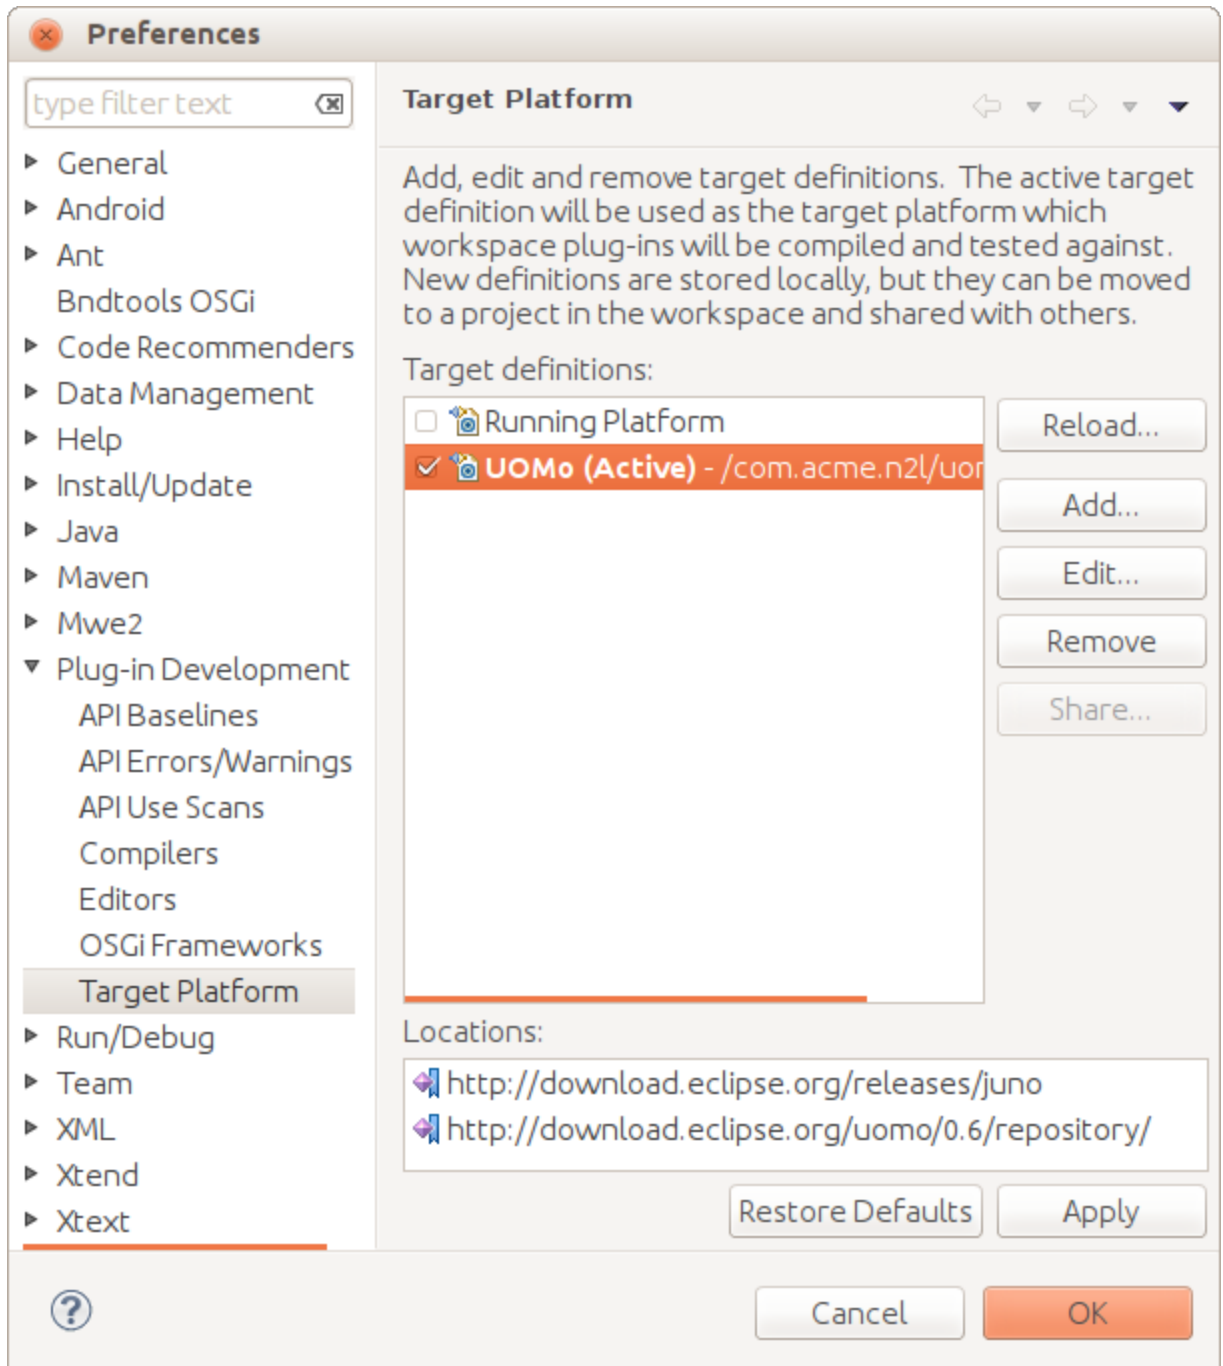

Now we need to add the UOMo libraries to our target. Click "Add.." again on the target platform editor window. The select "Software Site" again. But this time enter the URL <http://download.eclipse.org/uomo/0.6/repository/>

Select the EclipseUOMo feature.

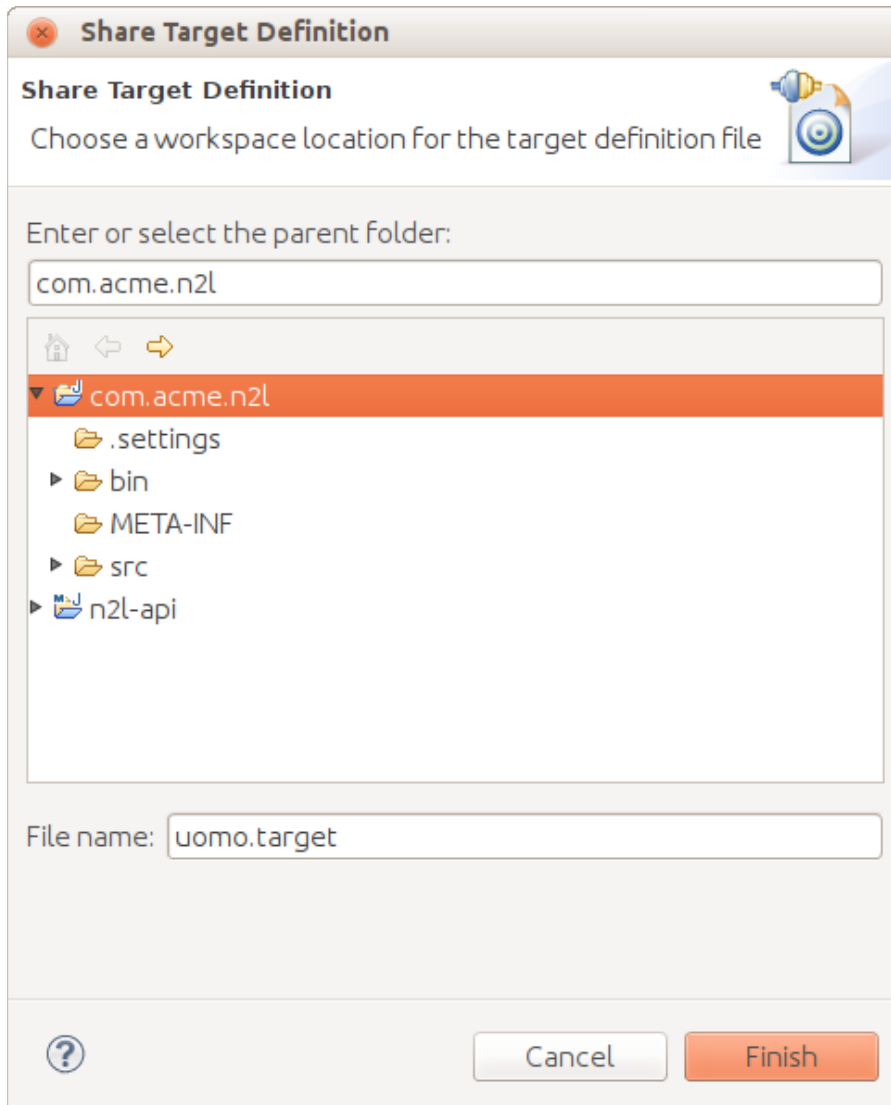

Click "Finish"

12. Eclipse will do some more loading/resolving. You are back at the target platform preferences page:

Select UOMo target and click “Apply”

13. (Optional) You can click “Share..” if you want to save this target definition as a file for use in the future. Pick a location and a name for the target file in the window as below:

Click “Finish” when you are done.

14. Click “OK” on the preferences page

15. Now you are ready to start work on our N2L plug-in.

Create a new class called `NewtonSecondLaw` in the package `com.acme.n2l`

Now add the following code:

```
package com.acme.n2l;

import org.eclipse.uomo.units.SI;
import org.eclipse.uomo.units.impl.quantity.AccelerationAmount;
import org.eclipse.uomo.units.impl.quantity.ForceAmount;
import org.eclipse.uomo.units.impl.quantity.MassAmount;

public class NewtonSecondLaw {
```

```

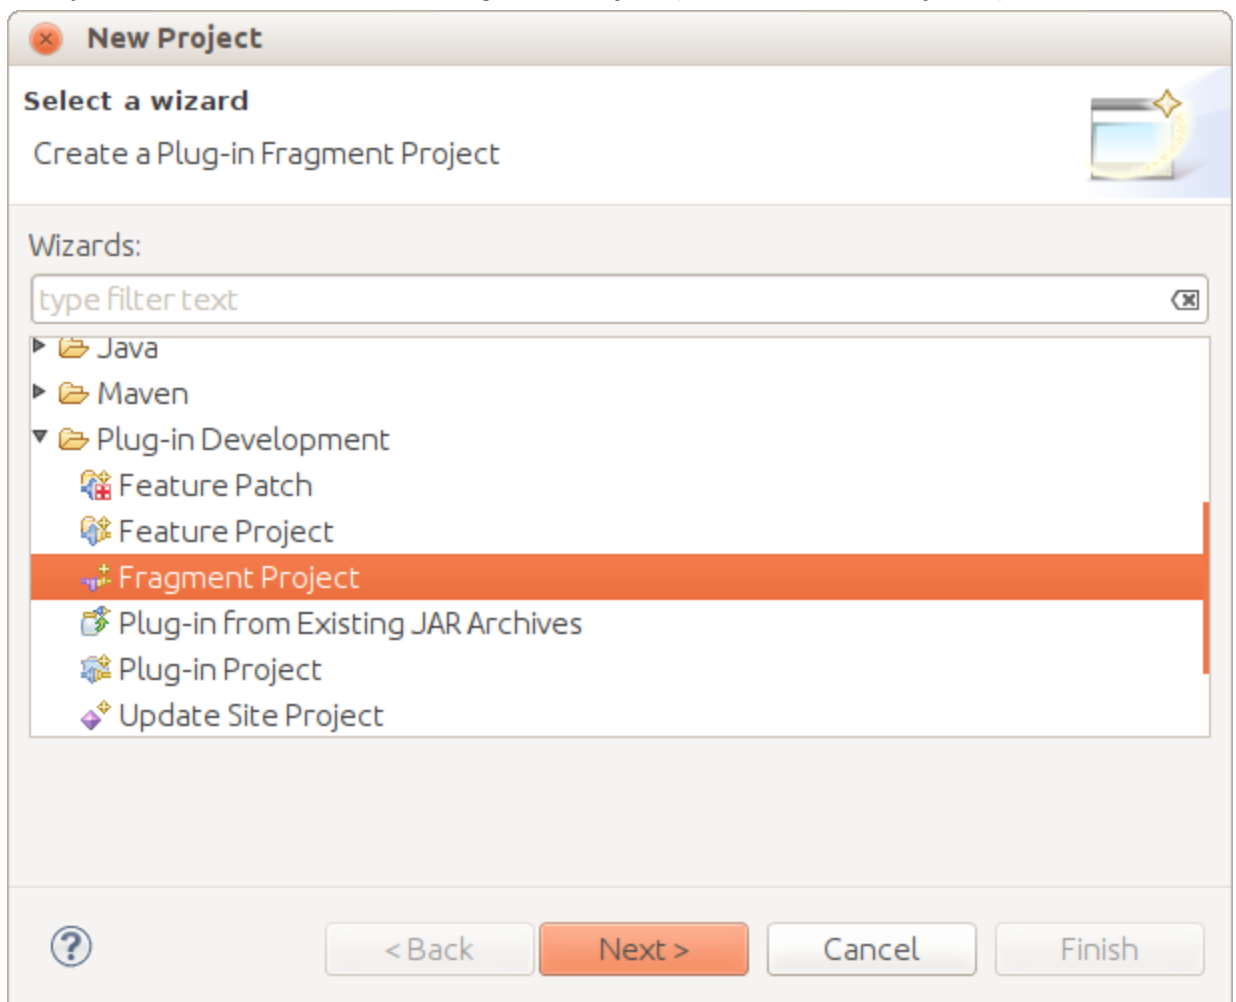

public static final ForceAmount calculateForce(MassAmount m, AccelerationAmount a)
{
    double m_kg = m.doubleValue(SI.KILOGRAM);
    double a_si = a.doubleValue(SI.METRES_PER_SQUARE_SECOND);
    return new ForceAmount(m_kg * a_si, SI.NEWTON);
}
}

```

The important part of this code is the `calculateForce` method; it takes as parameters an amount of mass and an amount of acceleration - and returns an amount of force. The units of these parameters are not defined; just that they are of quantity Mass and Acceleration respectively. So our code needs to get the absolute value of these in a known unit for calculation - for simplicity we use the SI units Kilogram (kg) and Metres per second per second ( $m/s^2$ ).

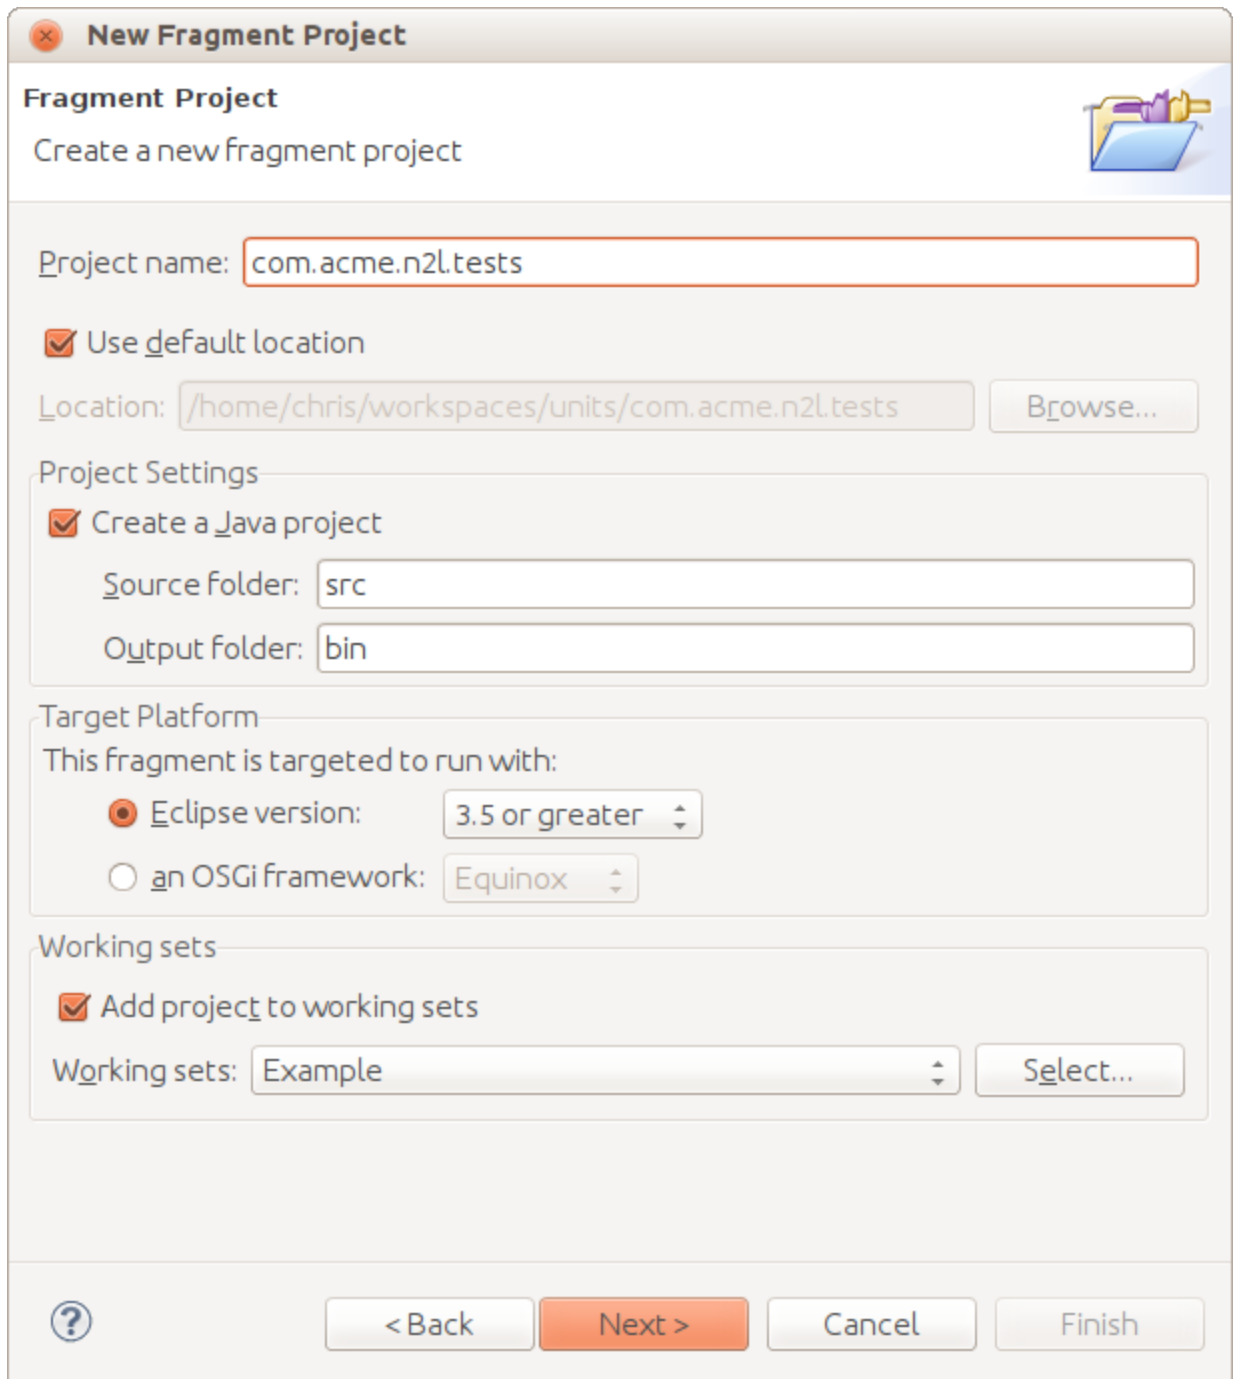

We then simply perform the multiplication, and create a result using the SI unit for Force - Newtons (N).

16. Now we are ready to test out our API with a Unit test. What follows is a little long winded thanks to how Eclipse Plug-ins do unit tests..
17. Firstly we need to create a New Fragment Project (File -> New -> Project...):

Click “Next”

18. Give the fragment the name of our main project with “.test” appended:

The screenshot shows the 'New Fragment Project' dialog box in the Eclipse IDE. The dialog has a title bar with a close button and the text 'New Fragment Project'. Below the title bar, there is a section titled 'Fragment Project' with a folder icon and the text 'Create a new fragment project'. The 'Project name' field is filled with 'com.acme.n2l.tests'. The 'Use default location' checkbox is checked. The 'Location' field shows the path '/home/chris/workspaces/units/com.acme.n2l.tests' with a 'Browse...' button next to it. The 'Project Settings' section has a 'Create a Java project' checkbox checked, with 'Source folder' set to 'src' and 'Output folder' set to 'bin'. The 'Target Platform' section has a radio button selected for 'Eclipse version:' with a dropdown menu showing '3.5 or greater', and an unselected radio button for 'an OSGi framework:' with a dropdown menu showing 'Equinox'. The 'Working sets' section has an 'Add project to working sets' checkbox checked, with a 'Working sets' dropdown menu showing 'Example' and a 'Select...' button next to it. At the bottom, there is a help icon, a '< Back' button, a 'Next >' button (highlighted in orange), a 'Cancel' button, and a 'Finish' button.

Click “Next”

19. We need to give the fragment a “host” that is our `com.acme.n2l` plugin:

**New Fragment Project**

**Fragment Content**

Enter the data required to generate the fragment.

**Properties**

ID:

Version:

Name:

Vendor:

Execution Environment:

**Host Plug-in**

Plug-in ID:

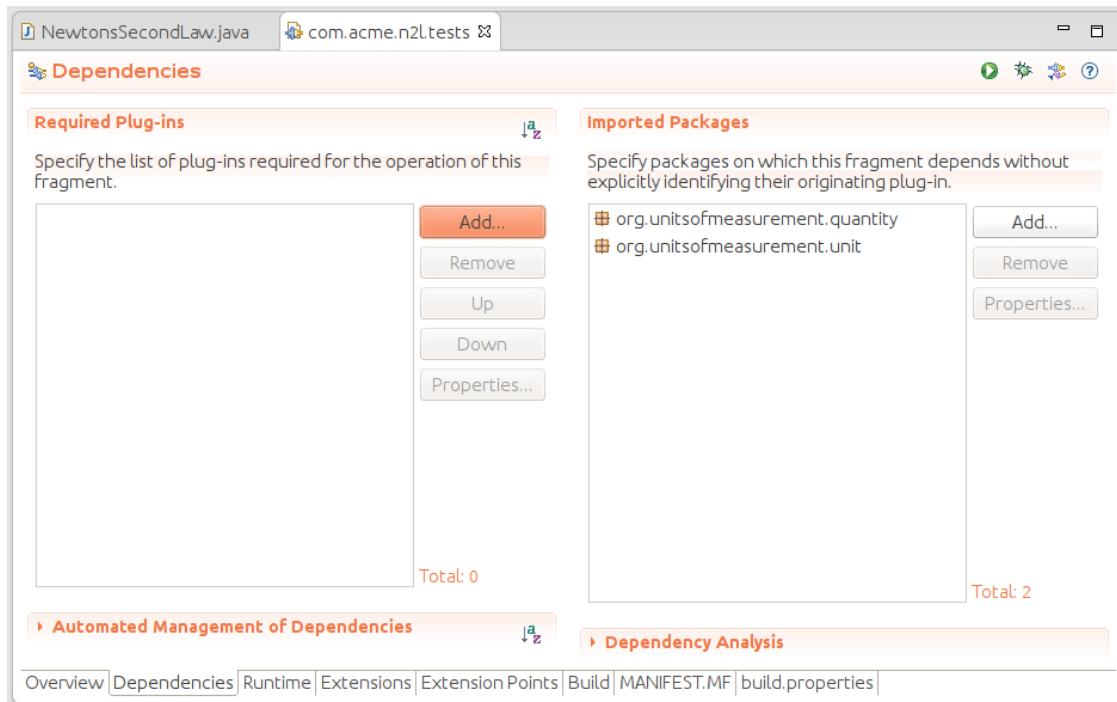

Minimum Version:

Maximum Version:

Click "Finish"

20. Now we need to add JUnit to the fragment's dependencies. Find and double click the META-INF/MANIFEST.MF file to open the fragment manifest editor. Select the "Dependencies" tab:

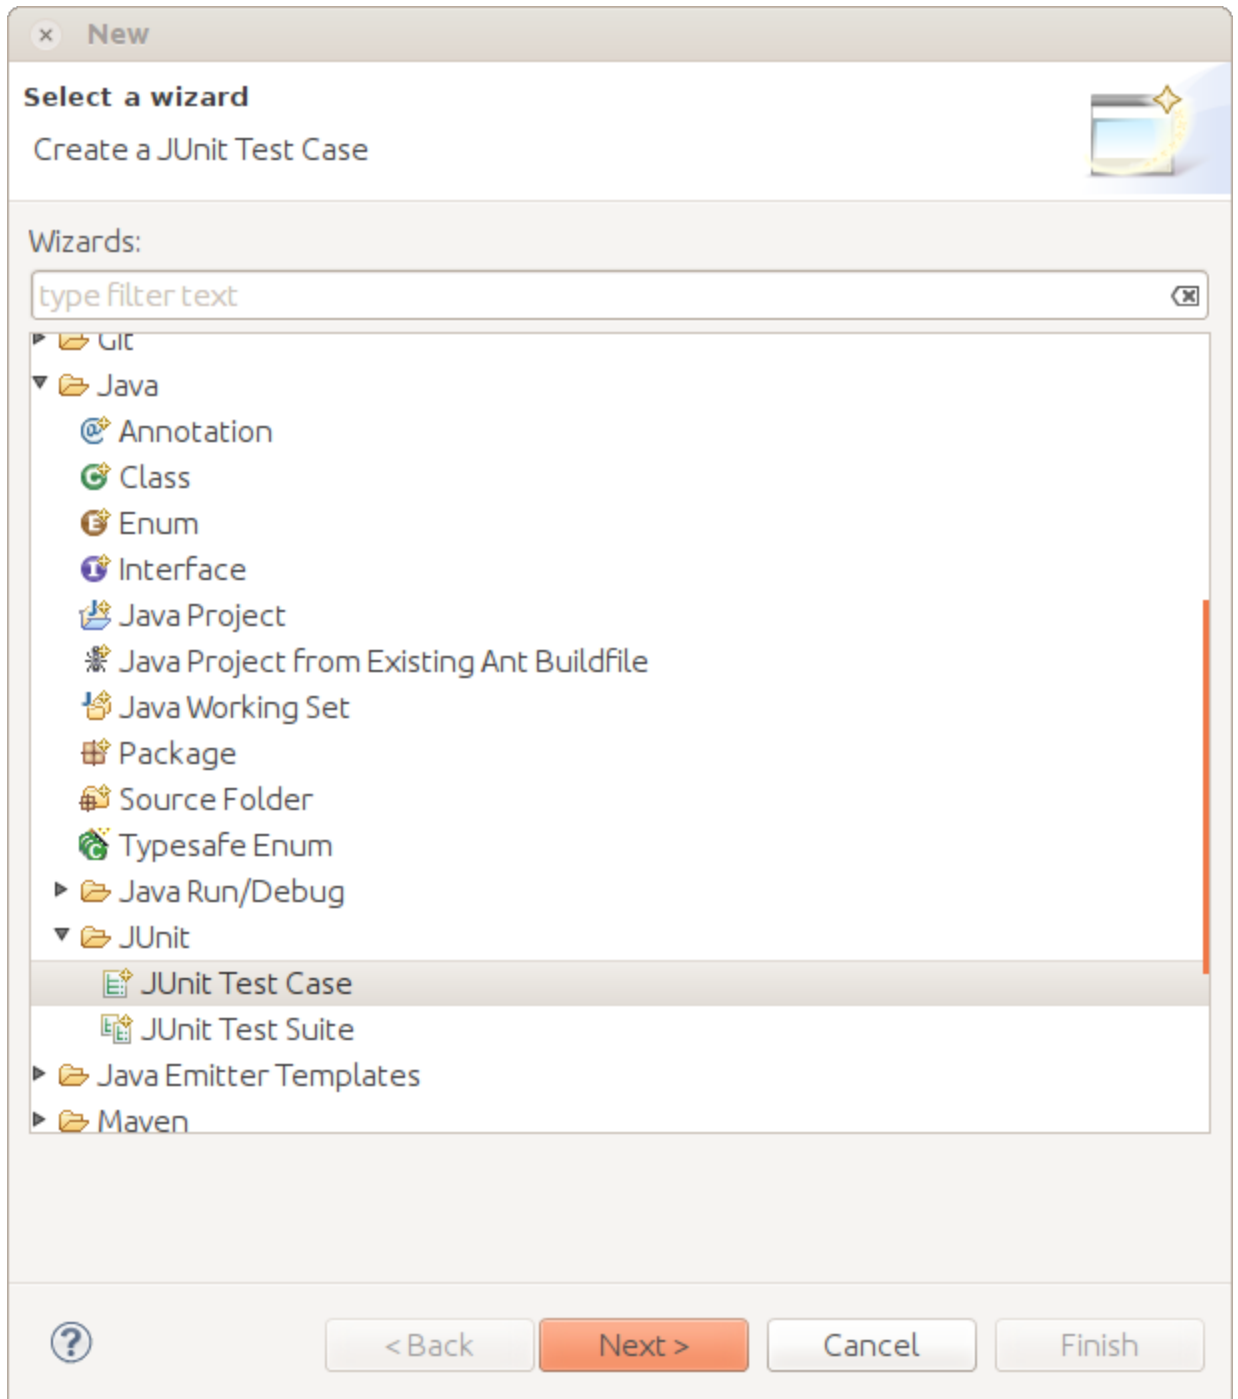

Click “Add...”

21. Enter “junit” in the search field:

Select the `org.junit` plugin and click "OK"

22. Now we create a unit test class in our fragment. Find and right click on our `NewtonSeconLaw.java` file and choose "New -> Other..." from the context menu.
23. Select Java -> JUnit -> JUnit Test Case from the dialog:

Click "Next"

24. Select the location for the unit test in the src folder of our test fragment. And select the calculateForce method for testing:

**New JUnit Test Case**

**JUnit Test Case**

Select the name of the new JUnit test case. You have the options to specify the class under test and on the next page, to select methods to be tested.

☐ New JUnit 3 test ☒ New JUnit 4 test

Source folder:

Package:

---

Name:

Superclass:

Which method stubs would you like to

☐ setUpBeforeClass() ☐ tearDownAfterClass()  
☐ setUp() ☐ tearDown()  
☐ constructor

Do you want to add comments? (Configure templates and default value [here](#))

☐ Generate comments

---

Class under test:

Click "Finish"

25. Now we need to replace the template test code with our own. Add the following:

```
@Test
public void testCalculateForce() {

    MassAmount m = new MassAmount(1000, SI.KILOGRAM);
    AccelerationAmount a = new AccelerationAmount(2.5, SI.METRES_PER_SQUARE_SECOND);
    ForceAmount force = NewtonsSecondLaw.calculateForce(m, a);
}
```

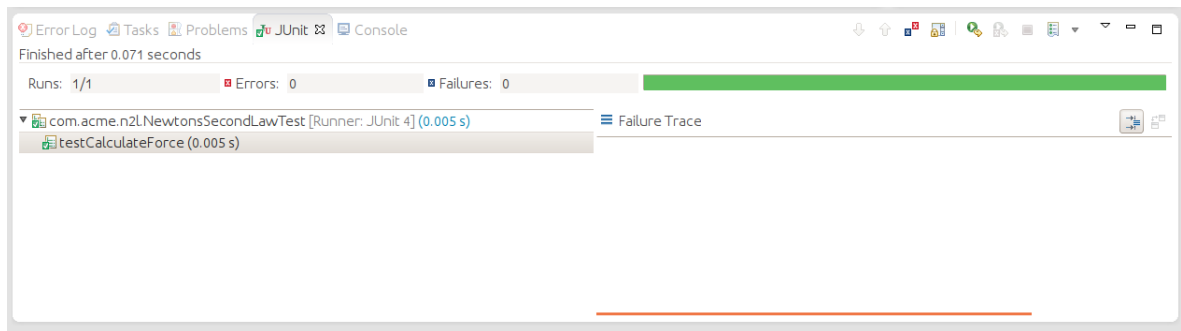

```

    assertEquals(2500, force.doubleValue(SI.NEWTON), 0.0001);
}

```

This method simply creates a 1000 kg mass, a 2.5 m/s<sup>2</sup> acceleration and asks our N2L class to calculate the force. We then assert that the calculated force is 2500 Newtons (+/- 0.0001).

26. Save the file and Right click on it - then choose “Run As -> JUnit Plug-in Test”. The test will run and you should see the JUnit results window appear:

27. You have now completed and tested your first simple UOMo project.

OK, so what....

Ok that's the basics out of the way now you can try a few things that demonstrate the power of UOMo and the Units of Measurement API...

1. Try changing the units used in your unit test for mass or acceleration to units of other quantities (i.e. seconds, metres, amperes, volts... ). You will see the compiler error created because your unit is not the correct type... cool!
2. Same is true when we try to extract a value - change the `force.doubleValue` line in the unit test to use units that are not a force... same, the compiler error because the unit is not for a force! cool!

This is important, it protects clients of your `NewtonSecondLaw` API from making mistakes when they create values to pass to you. They can only pass in legitimate masses or accelerations.

As an example we can add another test method to our test case:

```

@Test
public void testWithOddUnits() {
    // We create a mass in US Pounds!
    MassAmount m = new MassAmount(100, USCustomary.POUND);
    // Now let's create a whacky acceleration unit of our own...
    @SuppressWarnings("unchecked") // we know this creates an acceleration!
    Unit<Acceleration> inch_per_square_second =
        (Unit<Acceleration>) USCustomary.INCH.divide(SI.SECOND).divide(SI.SECOND);
    // Note our N2L API does not know this unit at all!
    AccelerationAmount a = new AccelerationAmount(100, inch_per_square_second);
    ForceAmount force = NewtonSecondLaw.calculateForce(m, a);
    // Yet our API is able to calculate the corresponding force without change
}

```

```
// Nice...
assertEquals(867961.6621451874, force.doubleValue(SI.NEWTON), 0.0000000001);
// Now let's try to get the result in a weird unit...
// The "pound-force" is a unit for Force in English engineering units
// and British gravitational units (http://en.wikipedia.org/wiki/Pound-force)
Unit<Force> poundForce = SI.NEWTON.multiply(4.448222);
// and we can now extract the result of our previous calc in that new unit!
assertEquals(3860886.16071079, force.doubleValue(poundForce), 0.0000000001);
}
```

Nice - our API can handle weird and wonderful unit values as input and we can extract weird and wonderful unit values as output! **Sweet!**
